Expose the lower part of the thigh, knee and upper leg. After skin and transducer preparation, place a linear transducer with the appropriate frequency range (10-12 MHz) starting in the proximal thigh and scan distally to the knee. The saphenous nerve can be blocked reliably in the distal 1/3 of the thigh.

The introduction of ultrasound-guided techniques and several studies supporting its use as an alternative to femoral block for total knee arthroplasty have greatly increased the interest in the transsartorial (or “adductor canal”) approach to the saphenous nerve.

The procedure is similar to the previously described in the continuous ultrasound-guided block section in Ultrasound-Guided Cervical Plexus Block. Advancement of the needle in plane in a lateral-to-medial direction until the tip is adjacent to the nerve and deep to the gluteus maximus fascia should ensure appropriate catheter location.

Ultrasound-guided popliteal block has been shown to have a higher success rate, require less time to perform, and be associated with less peri-procedural pain when compared to using a nerve stimulator.

Ultrasound-Guided Popliteal Block

The block involves tracing the path of the nerve as it follows the femoral artery down the medial thigh and then blocking the saphenous nerve as it changes course and moves superficially beneath the sartorius muscle in the distal thigh. In this position it is “trapped” between adjacent muscles and presents a perfect target for the block.

Neuraxiom Ultrasound Guided Nerve Blocks

If all nerves cannot be seen initially, a regional approach to the ultrasound guided axillary block has been described. For this approach, the most common locations for the nerves are targeted. The region of the median nerve (location 1) is blocked first, attempting to separate the median nerve from the artery.
